

I was doing the controller system.

The first challenge is trying to find the code to control the paddle. The isKeyDown function.

But I found that it always can not fit in my code. So I research a lot. Finally I get the reason is the I need to write the words like this "KEY_left". And then I need to write the variable. The variable also got some problem. Can not using. I fix a long time. Finally I found I need to write static in front them. And then I need to give them a value.

I Also have a hard time using github too. My code always been cover by my old code for several times. I rewrite the code for many times. Finally I found I didn't write to the correct space and I didn't upload the current code. So it will cover my new code. This actually gives me a large problem.

When I writing the code, I also have a big trouble with identity the place of the paddles. I need to make sure the left paddles and right paddles can not move out of the screen and also need to make sure every paddle can not go over the center line.

And also I am not good at using github. And to do controller always need to combine many variables from other group member works. So it is a hard time to get them correct. And then at last I write directly in to the main program because it is a hard time working from my individual one..
